SECTION 1

SAFETY INFORMATION

WARNING.

Any person performing the procedures described in this manual will be exposed to hazardous voltages and the risk of electric shock.

Carver Corporation assumes that any person who removes the cover from the unit has been properly trained in protecting against avoidable injury and shock.

Therefore, the procedures described here are to be performed by qualified electronics service personnel only.

We recommend that the unit be tested only when line isolation is provided by an isolation transformer. The line cord of the unit must be disconnected and the power supply fully discharged before any components are replaced. Failure to do so may result in severe damage to the unit and the risk of electric shock.

The safety tests described below must be performed properly.

CAUTION:

Before returning the unit to the customer, one of the following safety tests must be performed.

1. Check the leakage current. Disconnect all signal path inputs and outputs. Connect the unit to 120 VAC supply and turn the power switch "ON". Using an ammeter, measure the current between each side of the linecord and chassis ground of the unit under test. If leakage current exceeds 0.5mA, the unit is defective.
2. Measure the resistance from either side of the linecord to chassis ground. If it is less than 500k ohms, the unit is defective.

WARNING - DO NOT return the unit to the customer if it fails one of these tests until the problem is located and corrected.

CAUTION

	CAUTION RISK OF ELECTRIC SHOCK DO NOT OPEN	
CAUTION: TO REDUCE THE RISK OF ELECTRIC SHOCK DO NOT REMOVE COVER (OR BACK) NO USER-SERVICEABLE PARTS INSIDE REFER SERVICING TO QUALIFIED PERSONNEL		

The lightning flash with arrowhead symbol within an equilateral triangle is intended to alert the user to the presence of uninsulated "dangerous voltage" within the product's enclosure, that may be of sufficient magnitude to constitute a risk of electric shock to persons.

The exclamation point within an equilateral triangle is intended to alert the user of the presence of important operating and maintenance (servicing) instructions in the literature accompanying the appliance.

SECTION 2 INTRODUCTION

This manual is intended for use by qualified, authorized personnel only.

Due to the unique and complex circuit designs of Carver Corporation, the following procedure is recommended to diagnose & repair problems with speed and accuracy.

The best way to figure out what is wrong is to learn what is working properly first. Then, through the process of elimination, the defective area can be located. Upon locating the defective area, you then would use your own preferred troubleshooting skills.

The removal of parts for testing, should be kept to an absolute minimum. "In circuit" analysis should provide you with enough data to determine correct operation.

Refer to the design history section of the service manual if you locate a part in the circuit that is not the same as the schematic. This section will be of great assistance to you in performing a correct repair.

At Carver Corporation we continually strive for the most reliable, cost-efficient product available.

When updates and service bulletins are sent to you, please take the time to review them and insert them into the correct service manuals.

The M-4.0t Magnetic Field Power Amplifier was released in April of 1988. The front panel was originally the Anodized Gray color that was characteristic of the Carver product line throughout the 1980's.

In July of 1989, the color of the front panel changed to Charcoal Black, which is now characteristic of the Carver product line in the 1990's.

In September of 1989 a limited number of TFM-4.0 amplifiers were produced as a transition to our TFM line of power amplifiers. The TFM-4.0 is the same as the M-4.0t except for the screening on the front panel.

In October of 1989, the TFM-42 and TFM-45 amplifiers were released. The basic amplifier design is the same as the M-4.0t; however, many cosmetic and auxiliary circuit changes were made to accommodate the new style front panels. Therefore, you will find separate schematics, board layout drawings and parts lists for the M-4.0t/TFM-4.0 and the TFM-42/45 amplifiers in this service manual. Please be sure you are referring to the drawings and parts lists that correspond to the model being serviced.

SECTION 3

SPECIFICATIONS

Specifications for the M-4.0t, TFM-4.0, TFM-42, TFM-45

Power Output:	
Continuous Average Output Power, Both channels driven:	375 watts per channel into 8Ω from 20 Hz to 20 kHz 500 watts per channel into 4Ω from 20 Hz to 20 kHz
Bridged-mono operation:	1000 watts per channel into 8Ω from 20Hz to 20 kHz
Power at Clipping, Both channels driven:	450 watts per channel into 8Ω at 1 kHz
Dynamic Headroom:	1.5dB @ 8 ohms 1.75dB @ 4 ohms
Frequency Response:	20Hz to 20kHz +/- 0.5dB
T.H.D.:	Less than 0.5%
IM Distortion:	Less than 0.15%
Noise:	-110 dB A-weighted, referenced to rated power -84.3dB A-weighted, referenced to 1 watt.
Input Impedance:	115kΩ 47kΩ after TFM-42 S/N 91110900001 TFM-45 S/N 91110400001
Sensitivity:	1.7V rms for rated power into 8 ohms
Damping Factor:	Greater than 7
Crosstalk:	Better than -45dB, 20-20kHz
Gain:	29.5dB (M-4.0t/TFM-4.0) 29.0dB (TFM-42/45)

Display:

Model	M-4.0t	TFM-4.0	TFM-42	TFM-45
Independent Clipping Indicators	X	X	X	
Protection LED Indicators	X	X		
Power Level LED Indicators	X	X	X	
Analog Meters				X

Size (H x W x D):	M-4.0t/TFM-4.0 TFM-42/45	3.5" x 19" x 10.5" (12.5" overall, including handles) 4.5" x 19" x 12.0" (14.25" overall, including handles)
Weight:	M-4.0t/TFM-4.0 TFM-42/45	23 lbs 25 lbs

Test Note: Accurate measurement depends on a sufficiently "stiff" AC supply. The 60 Hz AC line distortion must be below IHF specifications.

SECTION 4

CIRCUIT DESCRIPTION M-4.0t, TFM-4.0, TFM-42, TFM-45

TECHNICAL DESCRIPTION

The unconventional design of this amplifier is described in the following circuit description. Read this information carefully before attempting to repair this unit.

This circuit description is based on the TFM-45 amplifier. Any part of the circuit that is unique to the M-4.0t, TFM-4.0, TFM-42 or TFM-45 will be identified as such.

The M-4.0t, TFM-4.0, TFM-42/45 amplifiers consist of four types of circuit boards:

- * Amplifier
- * Primary Circuit and Regulator
- * Display
- * Main Power Supply, Protection and Input Circuits

Refer to the Block Diagram in Section 7 for an illustration of the functional relationships between system components, and to the complete schematic diagrams in Section 8 for the Amplifier, Power Supply, Regulator and Display Boards.

Primary Circuit and Regulator Board

The amplifier is fused with an MDA 12 amp fuse on the 115 V units and an MDA 6-1/4 amp fuse on 230 V units.

The amplifier is thermally protected by a heatsink mounted 100° C self-resetable thermal breaker in series with the transformer primary. Later versions of the TFM-42/45 also have an internal 150° C resetable thermal switch inside the transformer, in series with the primary.

A line filter minimizes normal and common mode noise on the AC line between 0.15 and 30 MHz. It is also used to suppress noise generated by the triac conduction from the AC line.

A voltage conversion switch rewires the transformer primary from a parallel to a series configuration for 230 V operation.

Start-up Sequence

The phase shift voltage at the junction of R8 and R2 is obtained through the heatsink thermal switch and is approximately 110-120V, regardless of whether the switch is in the 115V or 230V position.

The power switch on the front of the amplifier opens the connection from S to K on the Regulator Board, preventing the phase shift voltage from reaching the triac control circuit. (Note: The M-4.0t and TFM-4.0 use a different method of turning on the amplifier. When the power switch is off, it shorts the connection between D and E on the Regulator Board, preventing the phase shift capacitor C4 from charging up.) Once the power switch is turned on, capacitor C4 begins charging up through R8 and either Q2 or Q3, depending on the polarity. The positive half-cycle of the AC line will charge C4 through R8 and Q3. This charging current forward biases the base emitter junction of Q3, causing it to conduct. Q3 turns on Q4, but no gate current can flow because D6 is reverse biased. C4 continues charging until the charge on C4 exceeds the now falling voltage at the junction of the bases of Q2 and Q3, formed by divider R8 and R9. Q3 and Q4 will turn off and C4 will begin to discharge through Q2 because the junction of R8 and R9 is more negative than the emitter of Q3 (C4). Q2 will conduct and turn on Q1, and gate current will flow through forward biased D5, firing and latching the triac. On the negative half cycle, C4 is charged through Q2 and discharged through Q3, Q4, D6 and R10 into the gate of the triac. The triac begins to conduct at a minimum phase angle and applies 30-40 VAC to the primary of the transformer.

The triac is switched on and off every half-cycle of the 60Hz AC line. Thus, the triac switches the AC line current off at a rate twice the line frequency, at the instant the line current crosses the zero axis. The triac will then remain off for a number of degrees of the sinusoid, before switching on again. The phase angle at which the triac switches on is the "firing angle" of the triac.

This produces enough voltage to the primary of the power transformer to allow the secondary regulator stage on the power supply board to begin to operate.

Power Supply Regulation

The firing angle of the triac controls the voltage on the primary of the transformer, and is determined by the conduction of the optocoupler U1 on the Regulator Board.

As the conduction of the optocoupler increases, the amount of phase shift on C4 decreases, which increases the conduction angle of the triac. The phototransistor conduction of the optocoupler is controlled by the current through the LED portion of the optocoupler. This LED current is supplied by U1-7 on the power supply board. This differential amplifier senses the secondary supply voltages through R1, R4, R5 and R7. The output voltage at U1-7 increases at the rate determined by C3 (slow start-up). The photo-transistor in the optocoupler will begin to conduct and charge C4 on the regulator board at a faster rate through R2 and D1/D4 or D2/D3 "steering" diodes, depending on the polarity. This decrease in phase shift results in a longer triac conduction time and higher secondary voltages. The idle secondary voltages are set by RP1 on the power supply board.

Load Regulation

When either amplifier channel, or both are driven into a load (8 or 4 ohm), the DC supplies (rail voltages) will begin to "sag". Differential amplifier U1-1 senses this and increases the LED current to the optocoupler. This action increases the phototransistor conduction, which increases the triac conduction, which increases the primary voltage, which increases the secondary voltages, thus providing steady, regulated DC supplies for the amplifier stage.

Secondary Voltages

The secondary winding of the power transformer has three taps that supply the three pairs of DC supply voltages (+/-118V, +/-67V, +/-31V), each having its own bridge rectifier and filter capacitors.

Parallel load resistors R43 and R51 on the 31V bridge rectifier insure that the triac remains latched by providing primary holding current after the secondary supply rectifiers stop conducting.

Parallel load resistors R69 and R70 (TFM-45 only) load the -31Vdc supply to compensate for the added load of the meter lights on the +31Vdc supply. This allows for symmetrical discharging of the power supply at turn off, to minimize thumping or popping.

The +/-11.4Vdc supply are derived from the +/-31Vdc supply, and regulated by Q9, Q10 and zener diodes D22 and D23. Resistors R44, R46, R49 and R54 provide a residual DC voltage after the unit is turned off, thus keeping the front end of each amplifier biased up to prevent excessive thumping. The +/-11.4Vdc supply powers the op-amps and small-signal transistors.

The +/-13Vdc supply is also derived from the +/-31Vdc supply, using R48 and R50 to drop the 31V supply down. The +13Vdc is further regulated by zener diode D28 (not present in models M-4.0t and TFM-4.0). The value of R48 varies depending on the model due to differences in load current from the +13V supply. The +/-13Vdc supply powers the meter boards only.

Amplifier Stage:

Two standard phono jacks on the power supply board are capacitively coupled to the amplifier boards. The left channel has a unity gain inversion stage that is selectable by Switch S1-1, located on the power supply board and accessible through a hole in the rear panel. This switch allows the unit to be used in a mono-bridged configuration.

Both channels have an N-channel FET (Q1) that mutes the input approximately -30dB during turn-on or during a fault condition. The FET's share a common drive circuit that is located on the power supply board.

Input buffer U1 is a TL081 operational amplifier, which provides a high input impedance and a low output impedance for driving the clipping LED circuit (Headroom Exhausted LED's; not present on the TFM-45), and the succeeding amplifier stage. Local negative feedback from the output of U1 via R14 and C15 is used for stability and to reduce overall negative feedback.

The output of the input buffer U1 is coupled to Q2 and Q3 provide DC-level shifting. This is required for referencing the audio signal to the top DC supplies to drive the next stage.

The output of the DC-level shifters drives a pair of predriver voltage amplifiers (Q4 and Q7). This stage provides full voltage swing to the following current gain stages and also provides "tracking" to the commutator circuits.

The bias network of Q5 and Q6 provides adjustment of the DC idle current through outputs Q20 and Q22. Q6 is mounted on the heatsink and provides feedback to prevent thermal runaway and helps maintain a constant idle current. RP1 adjusts the idle current by varying the base voltage at Q6.

The predrivers (Q4 and Q7) drive the "driver" stage (Q11 and Q12), which in turn provides current amplification for driving the outputs and supply commutating circuitry.

Q9 and Q10 limit the current available to the base of the drivers. These transistors are biased on by the voltage drop across the output emitter resistors, R94 and R95. When Q9 is conducting, it provides a shutdown signal to the power supply board and mute circuitry. (See High Frequency Output for details.)

Current from Q11 and Q12 drives the two high gain, high-linearity output devices Q20 and Q22. These devices provide full voltage swing and current drive to the loads.

The active, local bias network of Q21, R87, and R88, provides variable "pull down" of the bases of Q20 and Q22 to help prevent common-mode conduction of the output transistors and reduce their turn-off time.

The TFM circuitry is composed of IC U2, which detects the output current by differentially detecting the voltage drop across R97. When an 8 ohm load is connected to the amplifier output, the output of U2 reduces the overall gain of the amplifier by approximately 0.88dB. At higher frequencies, C7 compensates for amplifier phase shift. When an 8 ohm load is connected, an additional 0.22dB is dropped across the 0.2 ohm 20W output resistors for a total attenuation of 1.1dB.

Power Supply Commutators

The first supply commutator transistors, Q19 and Q23, are used to increase the supply voltages on the collectors of Q20 and Q22 from 31 V to 67 V as required.

The diode network of D18, D19, and D20 (and their negative equivalents), on the base of Q20 and Q22, provides voltage "lead" for the first supply commutating transistors (Q19 and Q23). This allows the supply voltages to anticipate audio demand. As frequency increases, Q19 and Q23 require additional "lead" time to stay ahead of the audio. This is achieved by C22, R60 and D17 (and their negative equivalents). D29 and D30 prevent the first commutator from dumping back into the 31V supply.

The second supply commutator pairs (Q17 and Q18, Q24 and Q25) increase the supply voltages on the collectors of Q19 and Q23 to increase Q20 and Q22 collector voltages to 118 V (no load), as required.

The second commutators receive their drive from drivers Q14 and Q16. However, the current gain at this stage is insufficient to supply enough current to the output transistors, and a bootstrap network and current gain stage are required. The main bootstrap network consist of R49, R52, R62, and C19 (and their equivalents on the negative side).

The turn-on threshold for the second commutators is determined by the DC biasing on the base of Q13 and Q15.

D28 and D31 provide supply steering which prevents the commutators from dumping back into the 67V supply.

Protection Circuitry

Protection functions are shared by the amplifiers and the power supply. Active shutdown protection is provided for the following faults.

OVER CURRENT:

The amplifiers are protected from short-term excess current through the output stage by electronic current-limiters. When the current through the output transistors becomes excessive, the voltage drop across the emitter resistors R94 and R95 bias the current limiter transistors Q9 and Q10 on, which shunt the drive current via D7 and D9. Q9 provides base current for Q2 on the Power Supply Board through D8 and R37, which drives Q3. Q3 then charges C11 and turns on Q8, which supplies a negative turn-off voltage to the input muting FET's on the amp boards. This attenuates the input signal, removing the high current condition, turning off all but Q8, which turns off about four seconds later, after C11 discharges through R35 and R34; thus turning off the muting FET's and allowing signal to pass. In this way, the short circuit current is briefly limited to 16 amps until the mute circuit is activated. R56, D13, R57 and D14 determine the V-I limits. The limiters should not activate into loads of 2 ohms or greater with no more than 45 deg phase shift.

Q3 also biases on Q1 (M-4.0t and TFM-4.0 only), lighting the Protect LED. C4 is also charged and continues to provide base current to Q1, keeping the LED lit during the mute time.

DC OFFSET:

DC offset is sensed by a low-pass differential amplifier located on the power supply board, formed by U1-pins 2 and 3. Left and right amplifier outputs are summed by R22 and R23, and capacitor C6 rolls off the output in the audio spectrum while +/- DC offset and single channel low frequency signals below 5 Hz are amplified. If pin 1 goes positive, current through D6, R18, and U1-6 drives the output of U1-7 negative. This reverse biases the optocoupler LED on the Regulator Board and forces the conduction angle of the triac back to its initial startup position, thereby lowering all secondary power supply voltages and insuring the offset is held to a minimum value.

HIGH FREQUENCY OUTPUT:

The amplifier is not designed to protect the speaker at frequencies below 6 KHz. The amplifier drives to clipping at 10 KHz. At 20 KHz the amplifier drives to approximately 49 Vrms, or 1dB below clipping. C11 on the Amplifier Board forward biases limiter transistor Q9 during negative transitions. Q9 provides base current for Q2 on the Power Supply Board, thus initiating the input muting circuit. This attenuates the high-frequency signal, allowing the mute circuit to reset after a few seconds.

LOW-LEVEL SUPPLY:

D2 and D3, on the Power Supply Board, insure that the output of U1-7 never goes to its maximum positive state if the -11.4V or -13V DC supplies are shorted out.

If the output of U1 were to reach its maximum (+10 to +11V DC) at idle, the triac would shift to its maximum conduction angle and cause overvoltage in the 115V, 67V, and 31V DC supplies.

Any +11.4V DC supply fault causes DC offset at the amplifier output. (See DC Offset for a full description of the protective mechanism involved.)

OVERHEATED OUTPUT TRANSISTORS:

A 100° C resetable thermal switch, in series with the AC line, protects the output transistors if the top cover vents are blocked or if the unit is run with excessive continuous sinewaves.

OVERHEATED TRANSFORMER:

In later versions of the TFM-42/45, a 150° C resetable thermal switch is located between the primary and secondary windings of the power transformer. This switch protects the transformer when the amplifier is overfused or has a major fault condition.

MAJOR FAULTS:

The slo-blo line fuse protects the unit from further damage when a major fault such as a shorted triac, shorted transformer, or a major secondary power supply fault occurs.

If the unit is run at or near its rated power, the fuse eventually blows. The rated line fuse allows the unit to be operated without interruption for all musical applications.

Display Board:

(for the M-4.0t, TFM-4.0, & TFM-42)

The display consists of two columns of seven LED's each. The LED's in the left column monitor the peak output of the left channel. Similarly, the right-hand LED's monitor the right channel. In the following description the LED's are numbered from one to seven, bottom to top.

LED 1 indicates that power is on and the amplifier is ready for operation.

LED's 2 through 6 indicate power levels with a 1ms attack and 500ms decay.

This display operates by incorporating a series of four comparators and a resistive ladder network which sets the appropriate reference voltages for each stage.

The Level LED display is driven directly from the amplifier outputs, with the attack and decay ballistics provided by D12, D13, R40, R41, C12, and C13.

LED 7 indicates the presence of distortion in excess of 1%.

The Clip LED drive transistors (Q4, Q5, Q6, Q7) are driven off the negative-going error output signal from U1 on the Amplifier Boards.

Analog Meter Display:

(TFM-45 only)

The meter drive PCB provides electronic meter calibration via VR401 & VR402. If mechanical meter alignment is needed to obtain a 0 wattage reading with no signal, then remove the two screws on the meter bracket and lift out both meters.

At the bottom center of the front panel of the meter is the mechanical movement alignment point. At full power adjust the meter pointer to the 375 watts position (looking straight in at meter).

The electronic meter calibration is done as follows:

A) Set the input signal levels for 54.8Vrms output into an 8 ohm load on both channels.

B) Adjust the trim pots on the meter drive PCB (located on the front panel) for a reading of 375 Watts on the meters.

M-4.0/TFM-4.0

SECTION 5

TEST PROCEDURE

M-4.0t, TFM-4.0, TFM-42, TFM-45

Use the test procedures described in this section to determine the overall performance of the amplifier. Before beginning the test, read the troubleshooting section to review the types of problems that may be identified by the test. Steps 7 and 8 of the procedure must be completed to ensure the unit meets safety requirements.

If you do not understand any of the following procedures, or if you do not have the equipment required to complete the tests, please contact the factory.

Required Equipment:

Oscilloscope(s)

Note: We recommend the use of two scopes. One scope should be isolated, with no secondary ground reference. Use this scope to observe triac waveforms on the AC line. The second scope can be used to observe the amplifier output and for secondary troubleshooting.

Distortion Analyzer

Variac, 20-30 amp

AC line current monitor

AC line voltage monitor

Two 8Ω load resistors, 500W each

Digital voltmeter

AC voltmeter

Safety Analyzer (Hi-Pot Tester)

Presets:

Follow the procedure described below to power up a damaged unit:

- A) Connect an input cable to each channel's input jack from the distortion analyzer signal output (set to 2kHz).
- B) Set the Variac to minimum.
- C) Set RP1 on the Power Supply Board for minimum VDC (turn the potentiometer fully counter-clockwise).
- D) Set RP1 on the left and right Amplifier Boards for minimum idle current (turn the potentiometer fully clockwise).
- E) Set the Audio generator to minimum.

Step-by-Step Procedure:

CAUTION

All primary waveforms must be viewed with an isolated, line triggered scope with no secondary ground reference.

Step 1. Bring the variac up slowly to approximately 60 VAC line (or to 120 VAC for 230 V units).

- A) AC current flow in line should be less than 0.25 amps.
- B) All front panel LEDs should be off.
- C) The start up voltages should be as follows:
 - 1) Approximately 20 Vdc for 118 Vdc supplies
 - 2) Approximately 2-3 Vdc for 11.4 Vdc supplies.
- D) Check amplifier channels outputs for DC offset less than 100 mV.

Step 2. Bring up the variac to approximately 85 VAC line (or to 170 VAC for 230 V units).

- A) Triac fires and there is a momentary surge of current.
- B) Ready LED's should light (Protection LED is off.)
- C) AC current flow in line should be less than 0.5 amps.
- D) Increase audio input to generate a 1 Vrms 2kHz signal at the amplifier outputs. Small cross-over notches should be present on sine wave output.
- E) Check triac firing for good symmetry.
- F) Check all VDC supply levels for power supply regulation:
 - 1) 118 VDC supplies should be approximately 92 VDC.
 - 2) 67 VDC supplies should be approximately 51 VDC.
 - 3) 31 VDC supplies should be approximately 23 VDC.
 - 4) 11.4 VDC supplies should be approximately 11.4 VDC.
 - 5) 13 VDC supplies should be approximately 8-9 VDC.
- G) Amplifier offset should be less than 30 mV.

Step 3. Increase Variac to 120 VAC (or 230 VAC for 230 V units).

- A) AC current flow should be less than 1.0 amp.
- B) 118 VDC supply should be approximately 97 Vdc.

Step 4. Adjust RP1 on the Power Supply Board to obtain a top rail voltage of 118Vdc.

- A) Observe normal triac idling conduction at MT2 (See Figure 1).

Step 5. Set Amplifier Idle Current.

Note: This adjustment should be made after the unit has been on at least two minutes at idle.

- A) Turn off the input signal. Verify no loads are connected to the outputs.
- B) Adjust RP1 on the left Amplifier Board for 2.5mV across both 0.05Ω, 5W emitter resistors, R94 and R95.
- C) Repeat Step 2 for the right channel Amplifier Board.

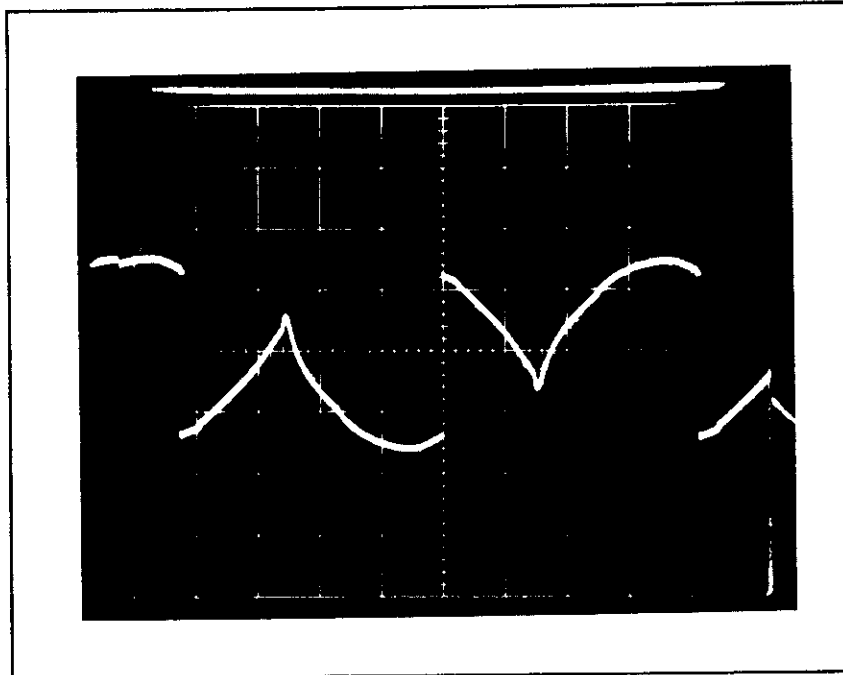

Figure 1: Triac conduction at idle, viewed at MT2.
(50V/div. Vertical; 2mS/div. Horizontal; Line Sync)

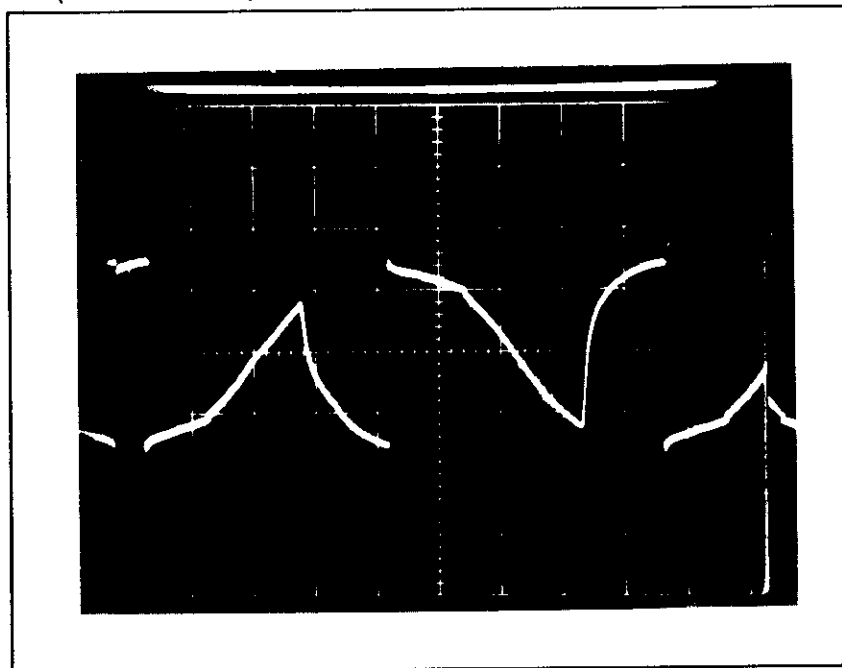

Figure 2: Triac conduction at full power, viewed at MT2.
(50V/div. Vertical; 2mS/div. Horizontal; Line Sync)

Step 6. Amplifier Boards.

A1) Adjust damping (TFM-42/45 only)

- 1) Connect an 8Ω load to the output of each channel.
- 2) Adjust the signal generator to produce a -29dBV (35.5mV rms) signal at 2kHz.
- 3) Adjust RP2 on each amp board to produce a 0dBV (1Vrms) output into an 8Ω load.

A2) Check Gain (M-4.0/TFM-4.0 only)

- 1) Adjust the signal generator to produce a -29.5dBV (34mV rms) signal at 2kHz.
- 2) Verify the output of both channels is 0dBV (± 1dB) into an 8Ω load. Left and Right channel outputs should be within 1dB of each other.

B) Check frequency response:

- 1) Set output reference to +10dBV (3.16Vrms) at 2kHz.
- 2) Check response at 20Hz and 20kHz (+0, -0.5 dB). See Figure 3.
- 3) Check mono switch for phase inversion of the left channel.

C) Verify separation at +10dBV, 2kHz is less than -45 dB.

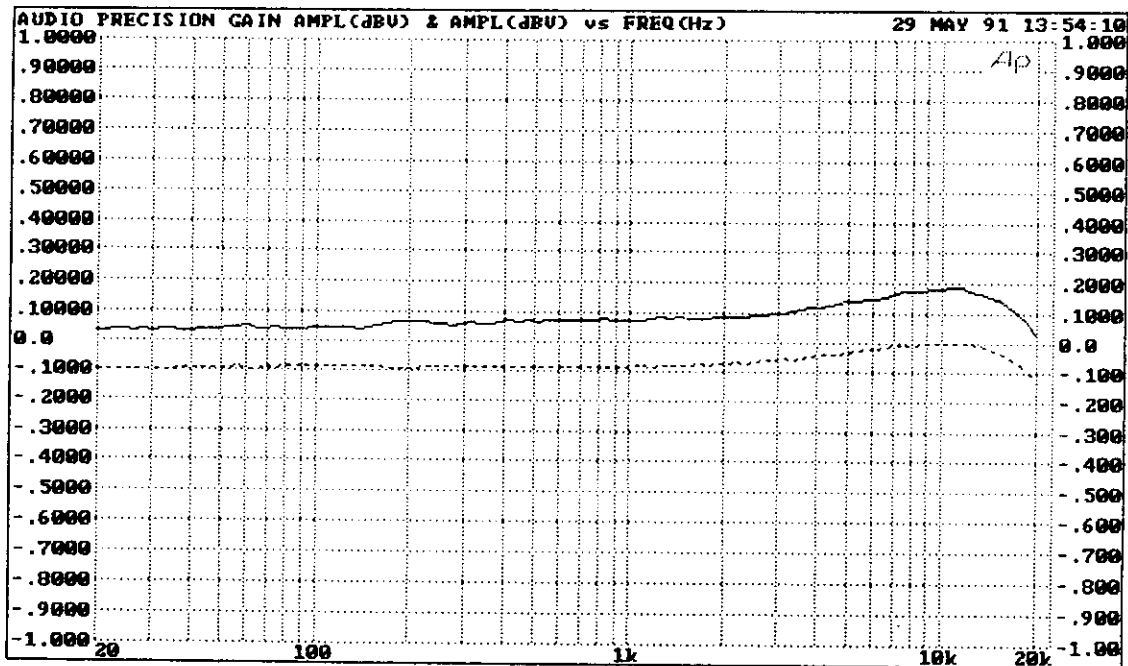

Figure 3: Frequency Response (Left Channel ———, Right Channel -----)

D) Check damping at 2kHz. Output should drop 1.0dB (± 0.1 dB) from no load to 8 ohm load.

E) Increase amplifier output to 54.8 Vrms (375W/8 ohms). Left and right channel commutators should appear as in Figure 4 at 2kHz.

NOTE: The AC line current will exceed the rated value of the line fuse when both channels are driven to full power. Since the fuse is slow-blowing, it can withstand the higher current for a few seconds before blowing. Therefore, these tests should be performed quickly to avoid blowing the fuse.

It may be necessary to temporarily replace the 12A line fuse with a 15A slo-blow fuse.

DO NOT forget to return the 12A fuse after completing these tests!

F) Check full power with both channels driven into 8 ohms at 2kHz (see Figure 5).

NOTE: A sufficiently low-impedance AC supply is required to achieve low distortion measurements at full power. If the AC line voltage "sags" at full power, it may be necessary to increase the Variac to bring the line voltage back up to 120VAC.

- 1) Note the maximum triac conduction angle at MT2, as shown in Figure 2.
- 2) Distortion at 375 watts per channel (54.8 Vrms) should be less than 0.2%.
- 3) Repeat at 20Hz and 10kHz.
- 4) Increase output to 405W (57 Vrms) and verify symmetrical clipping on the positive and negative peaks of the waveform.

G) High-Frequency Shutdown

- 1) Turn signal generator down and set to 20kHz. Slowly increase the input to the left channel and verify the output exceeds 40Vrms before the amplifier mutes (typically at about 50Vrms output).
- 2) Repeat for the right channel.

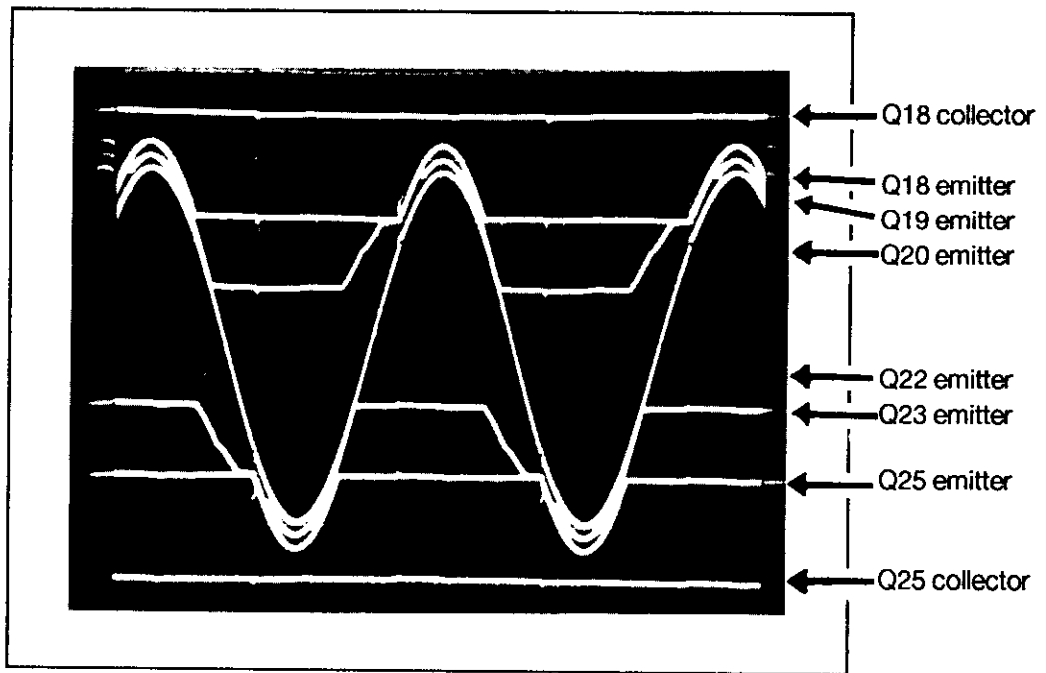

Figure 4: Commutators

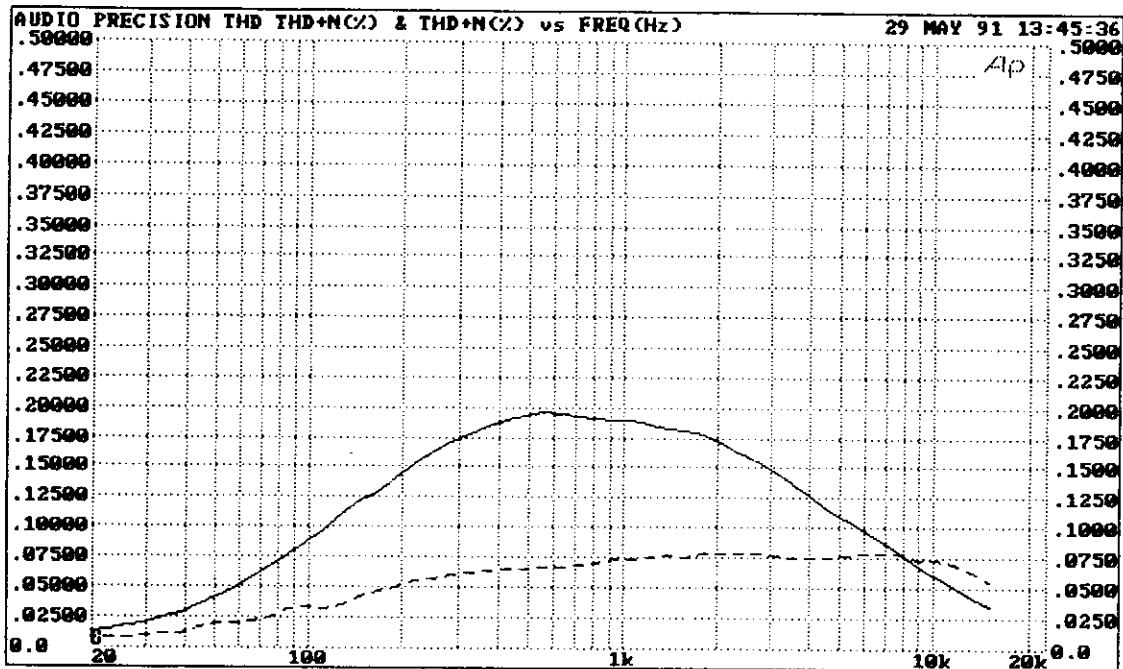

Figure 5: THD (A-weighted) vs. Frequency at full power (375W/8Ω)
(Left Channel —, Right Channel -----)

H) Short circuit protection:

- 1) Drive both channels at 2kHz to a 20 Vrms output.
- 2) Short left channel output to ground.
 - a) The amplifier should mute both channels immediately, and the protection LED should light.
 - b) One mute cycle should last approximately 4 to 6 seconds. Normal operation should return when short is removed.
- 3) Repeat Step 2 for the right channel output.

- I) DC fault protection:
 - 1) Short out the cathode of D22 on the Power Supply Board to ground. The amplifier should mute both channels and the Triac conduction angle should shift back to its startup position. The Protection LED will light on M-4.0t and TFM-4.0 models.
DC offset on both channels should be less than 10 Vdc.
Normal operation should resume when the short is removed.
 - 2) Short the anode of D23 on the Power Supply Board to ground. Verify same results as the previous step.
- J) Retest amplifier output:
 - 1) Check right and left channel outputs and displays from 0V to clip.
 - a) Display LEDs should be no more than ± 1 LED difference.
 - b) Check scope for the absence of distortion.
- K) Noise, with inputs shorted:
 - 1) Left and right channel noise A-weighted should be less than 110 dB below rated power ($< 175\mu\text{V}$) or less than 95dB below rated power unweighted (less than 1.0mV unweighted).
- L) Check turn-off and turn-on thump, and turn-on delay.
 - 1) Drive both channels at 2kHz to 0dBV output.
 - 2) Turn the amplifier off and verify a thump of less than 2Vrms (monitor for at least ten seconds).
 - 3) Turn the unit back on and verify less than 1Vrms thump, and the signal reappears between 4 - 10 seconds.
- M) Meter Calibration (TFM-45 only)
 - 1) With no input signal verify both meters read zero.
 - 2) Set the input signal level for 54.8Vrms output from the left channel into 8 ohms ($375\text{W}/8\Omega$).
 - 3) Adjust the pot (VR401) under the edge of the meter driver board for a reading of 375 watts on the meter.
 - 4) Repeat for the right channel, adjusting with VR402.
 - 5) Check that both meter lamps are lit and that the dimmer control operates properly (fully CCW is dim, full CW is bright).

Step 7. Line Leakage:

Before returning the unit to the customer, one of the following safety tests must be performed.

- A) Disconnect all signal path inputs and outputs.
- B) Connect the unit to 120 VAC supply and turn the power switch "ON". Using an ammeter, measure the current between each side of the linecord and chassis ground of the unit under test. If leakage current exceeds 0.5mA, the unit is defective.
- C) Measure the resistance from either side of the linecord to chassis ground. If it is less than 500k Ω , the unit is defective.

WARNING - DO NOT return the unit to the customer if it fails one of these tests until the problem is located and corrected.

Step 8. Dielectric Breakdown:

With an approved safety analyzer (Hi-Pot tester), verify that the unit can withstand application of a 1000 VAC signal for at least one second. Apply the signal between either side of the line and an exposed ground on the unit. The power switch should be ON.

SECTION 6

TROUBLESHOOTING GUIDE

The M-4.0t, TFM-4.0, TFM-42 and TFM-45 amplifiers are more complex than conventional amplifiers. This guide will help service technicians isolate and repair electrical faults in the amplifier.

Major faults should be investigated with the loads removed.

CAUTION:

All primary waveforms must be viewed with an isolated, line triggered scope with no secondary ground reference.

Fault 1: No Power.

No LED's Light at 120 VAC Line.

No AC Current.

- 1) Determine if AC line voltage is reaching the triac.
Use AC voltmeter from MT1 to MT2 on triac.
- 2) If AC is not present on triac:
 - a) Check fuse and fuse holder.
 - b) Check line cord.
 - c) Check voltage conversion switch on regulator board.
 - d) Check primary winding of transformer for continuity.
- 3) If AC is present across triac (MT1-MT2), but triac is not firing:
 - a) Check for phase shift voltage across C4 on regulator board.
 - b) If voltage is not present, either:
 - * The Power Switch is shorted (M-4.0t, TFM-4.0 only).
 - * Resistor R8 is open on the Regulator Board.
 - * Q2 and Q3 are defective on the Regulator Board.
 - * Check thermal switch on heatsink (normally resets after cooling).
 - c) If voltage is present, either:
 - * The triac is defective.
 - * Q1 and Q4 are open on the Regulator Board.
- 4) Triac fires and the voltage at C4 is less than 4 Vrms.
All power supplies remain low.
 - a) Check for shorted output transistors or driver transistors.
 - b) Opto-coupler CNY17-2 is defective.
 - c) D1 through D4 are defective on the Regulator Board.
 - d) U1 is defective on the Power Supply Board.
 - e) See Fault 4.

Fault 2: Greater Than 1 Amp AC Line Current Draw With Small Variac Rotation.

- 1) Check the following primary components:
 - a) Triac
 - b) Power transformer
 - c) Line filter
 - d) Voltage conversion switch
- 2) Check scope isolation.
- 3) Proceed to next section.

Fault 3: All LED's Fail to Light.

AC Line Current Greater Than 1 Amp After Triac Firing.

NOTE: This condition means that a current drawing fault exists on either the Power Supply Board or one or both Amplifier Boards. If only one channel is offset, then the fault is probably an amplifier board problem. If both channels are offset, then the fault is probably a common power supply fault.

Troubleshooting under these conditions can be simplified by shorting across the triac with a jumper wire. This bypasses the triac control and allows 100% of the line voltage to be applied to the transformer. Therefore, never increase the line voltage beyond about 60 VAC when the triac is bypassed.

Use Extreme Caution. Be sure the variac is turned all the way down, or better yet, unplug the amplifier from the variac. Short across MT1 and MT2, the cathode and anode of the triac. Do not short the gate of the triac or you may damage the triac and associated circuitry.

- 1) If the Amplifier channels are not offset:
 - a) Check 125 V supply capacitors and rectifiers.
 - b) Check 67 V supply capacitors and rectifiers.Observing excessive ripple voltage on any DC supply can help locate which supply is faulty.
- 2) If both channels are offset:
 - a) and the offset is positive:
 - * D23 is shorted on the Power Supply Board.
 - * C17 is shorted on the Power Supply Board.
 - * D14 and D15 are shorted on the Power Supply Board.
 - * C14 is shorted on the Power Supply Board.
 - b) and the offset is negative:
 - * D22 is shorted on the Power Supply Board.
 - * C16 is shorted on the Power Supply Board.
 - * D16 and D17 are shorted on the Power Supply Board.
 - * C15 is shorted on the Power Supply Board.
- 3) If one channel only is offset.
 - a) and the offset is positive:
 - * Q20, Q11, or Q21 is defective on the Amplifier Board.
 - * Q6 or Q5 is defective on the Amplifier Board.
 - * Check the predrivers Q4 and Q7 and associated resistors and diodes.
 - * The mica insulator on the Amplifier Board is defective or missing.

b) and the offset is negative:

- * Q22, Q12, or Q21 is defective on the Amplifier Board.
- * Q6 or Q5 is defective on the Amplifier Board.
- * Check the predrivers Q4 and Q7 and associated resistors and diodes.
- * The mica insulator on the Amplifier Board is defective or missing.

Fault 4: LED's Not Lit.

AC Line Current Draw is Less Than 1 Amp.

1) If one channel is offset.

a) and the offset is positive:

- * U1 is defective if the output is positive and if pin 3 is at ground and pin 1 of U2 on the Amplifier Board is at ground.
- * U2 is defective if pin 1 or pin 7 is offset on the Amplifier Board.
- * Q2 is shorted or Q3 is open on the Amplifier Board.
- * Q4 is shorted or Q7 is open on the Amplifier Board.
- * R34 is open.

b) and the offset is negative:

- * U1 is defective if the output is negative and if pin 3 is at ground and pin 1 of U2 on the Amplifier Board is at ground.
- * U2 is defective if pin 1 or pin 7 is offset on the Amplifier Board.
- * Q3 is shorted or Q2 is open on the Amplifier Board.
- * Q7 is shorted or Q4 is open on the Amplifier Board.
- * R32 is open.

Fault 5 : LED's Lit.

Power Supply Regulating. No Signal Amplification.

1) No output on either channels.

a) Mute drive defective.

- * Q8 on the Power Supply Board is open.
- * Q2 on the Power Supply Board is shorted.
- * Q1 on the left and right Amplifier Boards is shorted.

b) Defective current limiters.

- * Q9 on the left or right Amplifier Board is shorted.
- * D7 on the left or right Amplifier Board is shorted.
- * R94 or R95 have changed value or opened.

2) No output on one channel.

a) Mute FET Q1 is defective.

b) A bad solder joint at C3.

c) R3 is open.

d) Bad solder joint on the input jacks.

e) R97 is open.

f) 0.2Ω 20W Resistor (binding post) open.

Fault 6: Distorted Amplification One Channel (Commutation and Power Supply Fault)

- 1) First commutator is not supplying sufficient drive to the outputs:
 - a) Q19 or Q23 on the Amplifier Board is defective.
 - b) Either D29 or D30 is shorted. (This short causes the commutator current to flow back into the supply rather than to the output transistors.)
 - c) Insufficient voltage lead for the first commutator.
 - * Either D18, D19, D20, D21, D22, or D23 is defective.
- 2) Second commutator is not supplying sufficient current to the outputs.
 - a) Either Q17, Q18, Q24, or Q25 is defective.
 - b) Insufficient drive to Q17, Q18, Q24, or Q25:
 - * Check drive transistors Q13, Q14, or Q15, Q16.
 - * Check bootstrap network D12, D35, C19, R49, R52, R62, or D15, D36, C20, R61, R65.
 - * Either D28 or D31 is shorted. (This short causes second commutator current to flow back into the 71 V supply instead of to the output transistors.)
 - c) Current limiters are defective.
 - * Check D7, Q9 or Q10, or D9.
 - d) Drive circuitry is defective.
 - * Check drivers Q11 and Q12.
 - * Check R36 and R40.
 - * Check predrivers Q7 and Q4.
 - * Check fusible resistors R32 and 34.
 - * Check fusible resistors R35 and R41.
 - * Check D6 and D10.
 - * Check Q2 and Q3.

Fault 7: Drives No Load Ok. Distorts Into 4 Ω or 8 Ω Load.

- 1) Defective drive resistors on the Amplifier Board.
 - a) Check R36, R40, R35, R41, R32, and R34.
 - b) Check R23 and R26.
 - 2) Overheated emitter resistors.
 - a) Check output emitter resistors R94 and R95.
 - b) Check commutator emitter resistors R84, R93, R92, and R96.
 - 3) Leaky current limit transistors.
 - a) Check Q9 and Q10.
 - 4) Defective commutator transistors.
 - a) Check Q17, Q18, Q24, Q25, Q19, Q22.
 - 5) Defective commutator drive resistors.
 - a) Check R66, R74, R73, and R82.
 - b) Check R49, R52, R62, R61, and R65.
 - 6) If both channels are distorted, check the power supply rectifier.
 - a) Check BR1 for one diode open.
 - b) Check D14, D15, D16, and D17 for open.
 - c) Check D18, D19, D20, and D21 for open (or BR2 in later versions of the TFM-42/45).
-

Fault 8: Incorrect Damping

- 1) 0.2Ω 20W resistor in series with output is defective.
- 2) R97 on the Amplifier Board is defective.
- 3) U2 or R6-R15 is defective.
- 4) RP2 is misaligned on the amplifier board (except early versions of M-4.0t).

Fault 9: Excessive Noise

Note: With both inputs open, the right channel normally has more noise than the left channel. When the inputs are shorted or terminated, both channels are equally quiet.

- 1) Bad TL081 op-amp (U1) on the Amplifier Board causes "hiss" or "popcorn" noise.
- 2) Secondary leads from transformer are not routed downward close to the chassis.
- 3) Improper grounding.
 - a) Signal ground and power supply ground are connected somewhere in addition to the common grounding point on the power supply.
 - b) Transformer center tap (black wire), +118 V caps ground (black wire), speaker ground return (black wire) not soldered properly.
- 4) Bad FET Q1 on the Amplifier Board.
- 5) Triac misfiring causes excessive noise.
- 6) See noise reducing modifications in Appendix E, Service Bulletins.

Fault 10 : Excessive Turn Off "Thumps"

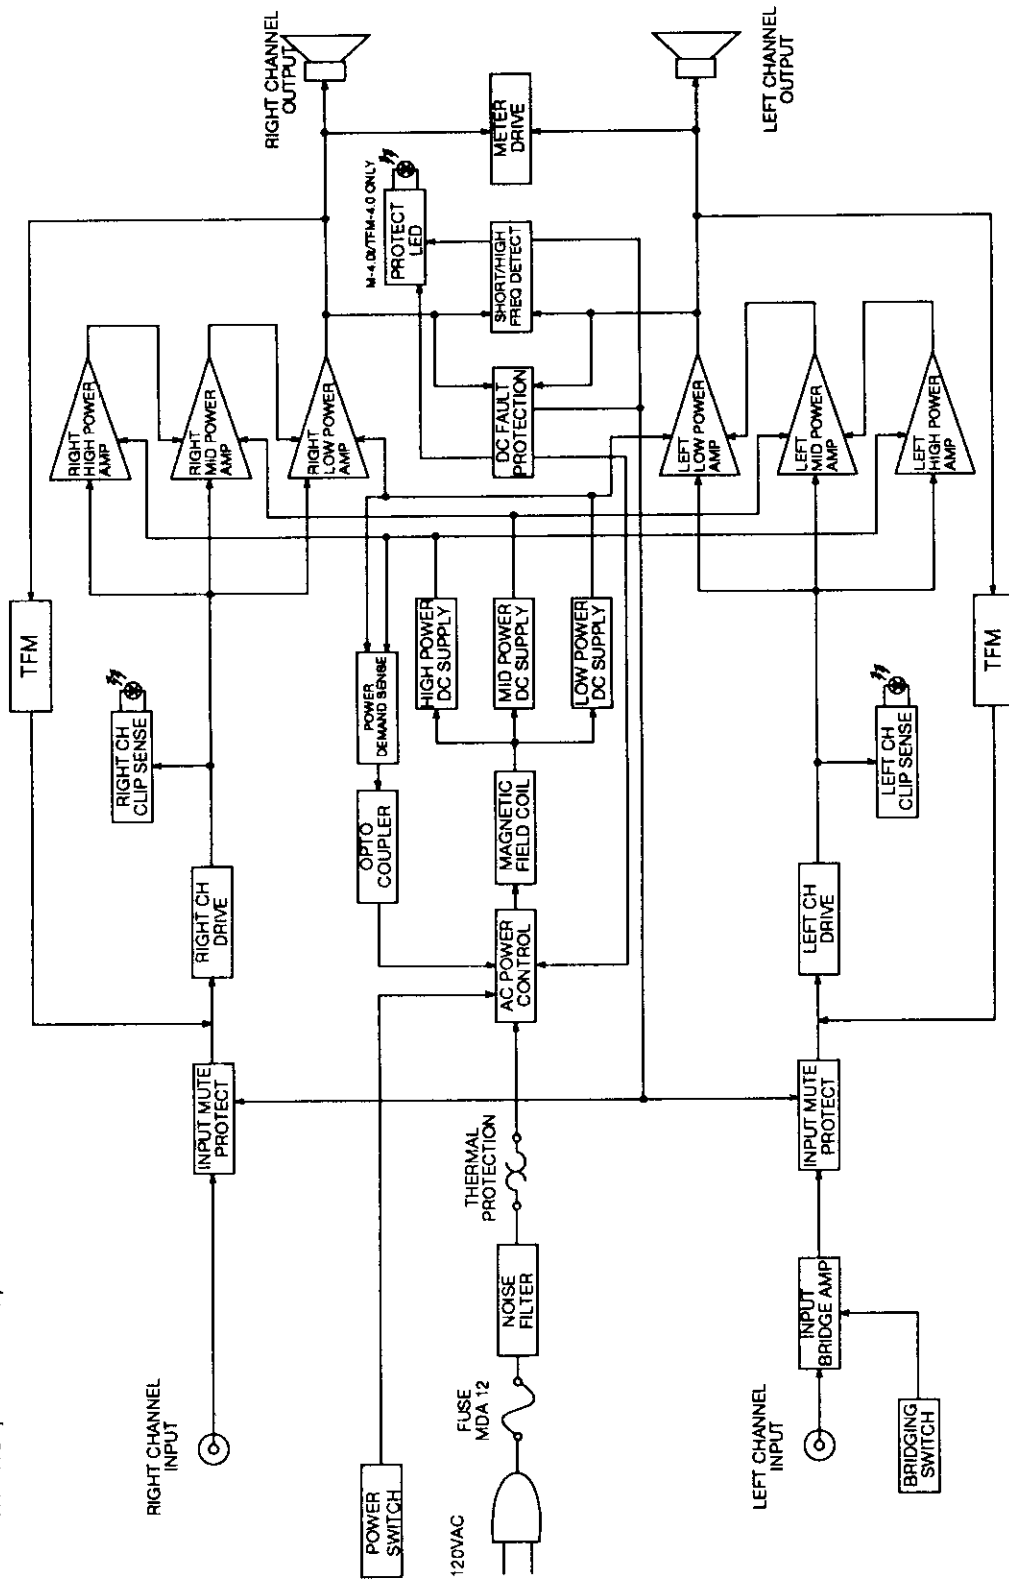

- 1) A delayed turn-off thump suggests a defective part in the low DC volt supplies:
 - a) Check R44, R49, R45, R55, R56, Q9 and C16.
 - b) Check R46, R47, R54, R57, R58, Q10 and C17.
- 2) Delayed turn-on and turn-off thumps indicate one of the following:
 - a) Defective TL081 on the Amplifier Board.
 - b) Leaky drivers or predrivers (Q4, Q7, Q11, or Q12).
- 3) For TFM-45 turn-on/turn-off thump, see Service Bulletin TFM-45-6 in Appendix.

Fault 11: High Frequency Oscillation

- 1) Output RC network at binding posts:
 - a) Check 2.7Ω 5W resistor.
 - b) Check 0.33μf 400 V capacitor.
- 2) Check the compensation capacitors, specifically:
 - a) Check C18, C8, C9, and C4.
- 3) Check the feedback networks, specifically:
 - a) Check C15 and R14.
 - b) Check C13 and R39.

1. ALL PARTS ARE 602-00576-00 PARTS JUST
 2. USE PCB TEM 10 REV F
 3. COMPONENT VALUES OF 2.4 OR VALUES TO BE MOUNTED ARE SHOWN BY A HCP
 4. COMPONENTS SHOWN IN DASH LINES ARE TO BE MOUNTED ON COMPONENT SIDE. SEE ITEMS A-A AND B-B.
 5. COMPONENTS SHOWN IN PHANTOM ARE REFERENCE ONLY AS SHALL BE INSTALLED AT FINAL ASSY.
 6. APPLY SEALANT TEM 1050 UNDER COMPONENT AS REQUIRED.
 7. SHOWN WITHOUT REFERENCE DESIGNATORS ARE NOT TO BE INSTALLED.

PRODUCT SAFETY NOTICE
 All safety precautions in this manual should be followed during servicing. Components identified with the IEC symbol Δ in the parts list and the schematic diagram designate components in which safety can be of special significance. When replacing a component identified with Δ , use only the replacement parts designated, or parts with the same rating of resistance, wattage or voltage that are designated in the parts list in the manual.

- 3. CAPACITANCE IS IN MICRO-FARADS.
 - 2. DIODES ARE IN14B.
 - 1. RESISTORS ARE 1/4W RESISTANCE 5 IN OHMS.
- NOTES: UNLESS OTHERWISE SPECIFIED

5. REF DESIGNATORS NOT USED: C1, C4, C5, C12, C13, C14, C15, C16, C17, C18, C19, C20, C21, C22, C23, C24, C25, C26, C27, C28, C29, C30, C31, C32, C33, C34, C35, C36, C37, C38, C39, C40, C41, C42, C43, C44, C45, C46, C47, C48, C49, C50, C51, C52, C53, C54, C55, C56, C57, C58, C59, C60, C61, C62, C63, C64, C65, C66, C67, C68, C69, C70, C71, C72, C73, C74, C75, C76, C77, C78, C79, C80, C81, C82, C83, C84, C85, C86, C87, C88, C89, C90, C91, C92, C93, C94, C95, C96, C97, C98, C99, C100.

REGULATOR BOARD
605-00560-00

NOTES:
1. RESISTORS ARE 1/4W, RESISTANCE 5% UNLESS OTHERWISE SPECIFIED.
2. DIODES ARE 1N4148.
3. CAPACITANCE IS IN MICRO-FARADS.
4. SEE TABULATION TABLE.
5. REF DESIGNATORS NOT USED: C1, C4, C5, C12, C13, C14, C15, C16, C17, C18, C19, C20, C21, C22, C23, C24, C25, C26, C27, C28, C29, C30, C31, C32, C33, C34, C35, C36, C37, C38, C39, C40, C41, C42, C43, C44, C45, C46, C47, C48, C49, C50, C51, C52, C53, C54, C55, C56, C57, C58, C59, C60, C61, C62, C63, C64, C65, C66, C67, C68, C69, C70, C71, C72, C73, C74, C75, C76, C77, C78, C79, C80, C81, C82, C83, C84, C85, C86, C87, C88, C89, C90, C91, C92, C93, C94, C95, C96, C97, C98, C99, C100.

- 1. WIRES TO BE SOLDERED CIRCUIT SIDE OF PCB, NOT COMPONENT SIDE
- 2. DO NOT INSTALL DIP DIP, D30, D21
- 3. ALL ITEMS ARE ON 602-00574-01 PARTS LIST, REV. A
- 4. ALL ITEMS ARE ON 602-00574-00 PARTS LIST, REV. K
- 5. WHEN INSTALLING R67, MAKE SURE TO KEEP AT LEAST 1/8" TO 3/4" AIR GAP BETWEEN RESISTOR AND BOARD.
- 6. JUMP LEADS OF R65 AND R55
- 7. COMPONENT NOT INSTALLED ON TRM 45 (-01), K77, K26, R50, R51, R52, R53, R54, D1, L1, C10, G4, D5, G4, D7, J1.
- 8. COMPONENTS NOT INSTALLED ON TRM 42 (-00) R46, R67, R44, G11, G12, D21, J1, J2, J3, J4, J5.
- 9. ALL ITEM NUMBERS 1000 AND ABOVE SHALL BE INSTALLED AFTER SOLDER DIP AT T40 LEVEL.
- 10. COMPONENT VALUES LESS THAN 100 SHALL BE MOUNTED FLUSH ON PCB. COMPONENT VALUES OF 100 OR MORE SHALL BE MOUNTED OFF PCB BY .15" MIN.
- 11. COMPONENT MOUNTED ON CIRCUIT SIDE OF PCB.

NOTES

- 1. All resistors are 1/4watts or 1/5watts 5% Resistor values are in ohms (K=1000ohms/M=1000Kohms)
- 2. All capacitor values are in microfarads (p=Picofarads)
- 3. Each D.C voltage shows the nominal values in volts no input signal.
- 4. MF-METALIZED FILM RESISTOR Tolerance F: 1% D: .5%

Section 9
APPENDICES

Appendix A
PARTS ORDERING

Please provide the Model numbers of the units involved when ordering genuine CARVER replacement parts. Also provide the CARVER part number and the generic part number to confirm the correct part needed.

The Carver Parts Department is open Monday thru Friday, 7:00 a.m. to 4:45 p.m. PST.

The following phone number is to be used for part orders only!

Technical assistance is not available on this line.

1-800-433-0547

Or if you prefer to FAX in your part order, please use the following FAX number:

1-206-775-9180

From time to time, when it is necessary, we may make a substitution for the original part ordered, due to circuit revisions or part availability.

Random deviation from the original CARVER designated part is not recommended!

Complete PCB replacement is not recommended. You must have prior approval for warranty repair should PCB replacement be necessary.

Appendix B PARTS LISTS

Appendix C DESIGN HISTORY

Engineering Change Orders for Model M-4.0t Magnetic Field Power Amplifier

Note: Revision levels for assemblies may be different than revision levels for parts lists and schematic diagrams.

ECO#:818	DATE: 08/12/88	REV.B Amp Board Assembly and Parts List - Effective S/N 61 REV.B Power Supply Board Assembly and Parts List REV.B Amp Schematic REV.B Power Supply Schematic
REASON FOR CHANGE:	Improve tube transfer function and commutator distortion.	
PROCEDURE:	On Amp Board change: C4, C15, R5, R11, R15 add: C22, C23, R60, R78 On Power Supply Board change: R16, R17, R60 add: C23, C24	
ECO#:844	DATE: 09/08/88	REV.E Final Assembly
REASON FOR CHANGE:	To reduce labor cost	
PROCEDURE:	Delete mica insulators and thermalcote from output transistors. Use sil-pads instead.	
ECO#:851	DATE: 09/21/88	REV.F Final Assembly - Effective S/N 246
REASON FOR CHANGE:	To reduce transformer buzz.	
PROCEDURE:	Add weatherstripping and black latex caulk. Modify transformer mounting technique.	
ECO#:852	DATE: 09/21/88	REV.E Amp Board Assembly REV.D Amp Board Parts List REV.D Amp Schematic - Effective S/N 246
REASON FOR CHANGE:	To improve frequency response.	
PROCEDURE:	Delete C7.	
ECO#:856	DATE: 09/27/88	REV.E Amp Schematic - Effective S/N 246 REV.E Amp Board Parts List
REASON FOR CHANGE:	To improve bias pot stability.	
PROCEDURE:	Change RP1 and R30.	
ECO#:873	DATE: 10/13/88	REV.F Amp Schematic REV.F Amp Board Parts List
REASON FOR CHANGE:	To prevent possible shutdown into low impedance loads.	
PROCEDURE:	Change Q9, Q10.	
ECO#:888	DATE: 11/16/88	REV.H Final Assembly - Effective S/N 821
REASON FOR CHANGE:	To prevent triac from misfiring.	
PROCEDURE:	Add 20k ohm 1W resistor to bridge rectifier (R68).

Appendix D

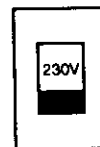

VOLTAGE CONVERSION FOR M-4.0t, TFM-4.0, TFM-42/45

Bill of Materials

Qty	Part Number	Description
1	315-13004-00	Fuse MDA 6-1/4A
1	315-13002-00	Fuse MDA 12A
1	530-10037-00	Label MDA 6-1/4A
1	530-10094-00	Label 230VAC 50Hz
1	530-20044-00	Label, Voltage Conversion (M-4.0t/TFM-4.0)
1	530-10136-00	Label, Voltage Conversion (TFM-42/45)
1	530-10013-00	Label, Military Conversion

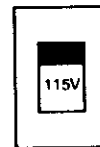

Directions for Change (115V to 230V)

1. Set the switch on the power supply regulator board to the 230V position.
2. Replace the MDA 12A fuse with an MDA 6-1/4A fuse (P/N 530-10037-00).
3. Attach the MDA 6-1/4A fuse label (530-10037-00) over the MDA 12A printing near the fuseholder.
4. Attach the 230VAC 50Hz label over the 120VAC 60Hz printing near the line cord.
5. Attach the Voltage Conversion label (P/N 530-20044-00 for M-4.0t/TFM-4.0; P/N 530-10136-00 for TFM-42/45) to the inside of the top cover. Do not block ventilation slots.
6. Attach the Military Conversion label (P/N 530-10013-00) to the rear of the chassis.

Directions for Change (220V to 115V)

1. Set the switch on the power supply regulator board to the 115V position.
2. Replace the MDA 6-1/4A fuse with an MDA 12A fuse (P/N 315-13002-00).
3. Remove the MDA 6-1/4A fuse label near the fuseholder.
4. Remove the 230VAC 50Hz label near the line cord.

SERVICE BULLETINS

Please insert Carver Service Bulletins pertaining to the M-4.0t, TFM-4.0, TFM-42 or TFM-45 here to ensure proper repair in the future.

CARVER CORPORATION SERVICE BULLETIN

Service Bulletin # M-4.0t-1

Model M-4.0t

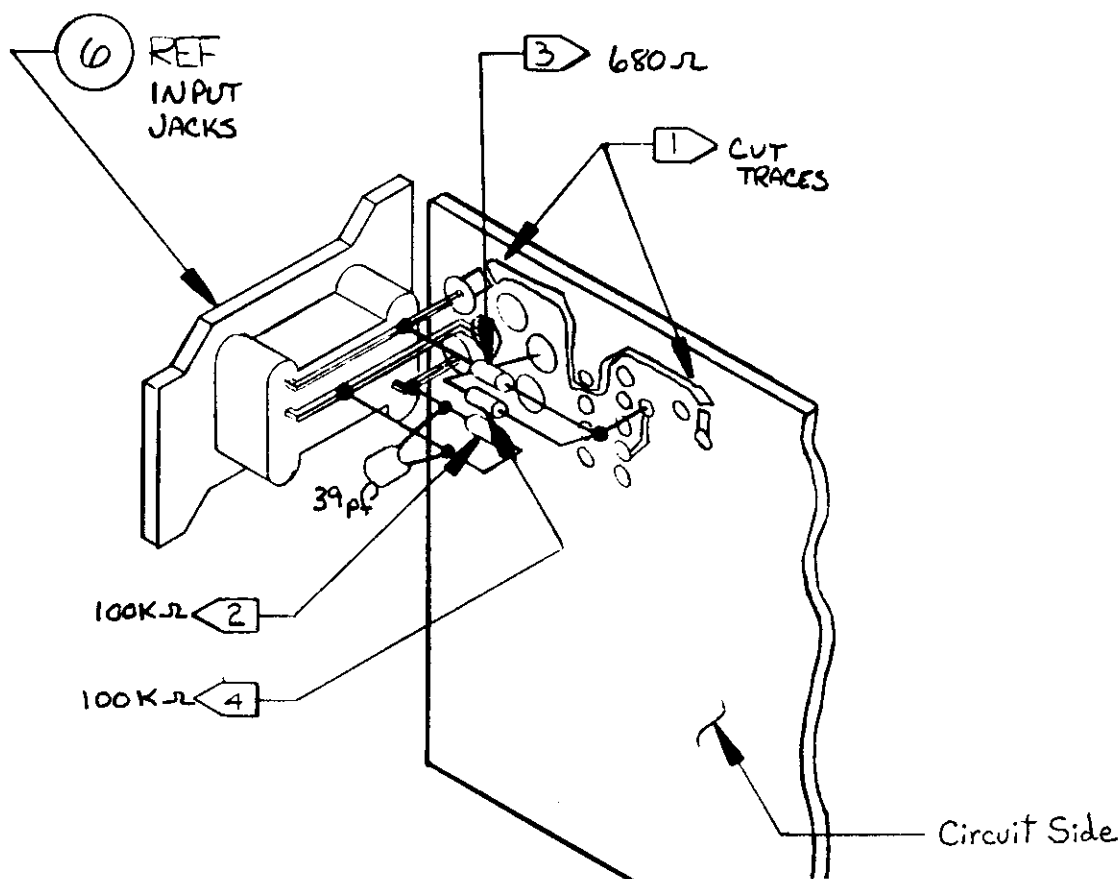

Serial # up to 1366

Reason: Too much "BUZZ" (60Hz) with input jacks unterminated.

Procedure: Route Transformer Secondary wire bundle behind terminal strip. Use a snake lug on back side of terminal strip to hold wires. On inside front transformer mounting bolt remove nut and scrape metal clean. Add a #6 solder lug and retighten mounting nut. Add 7 inches of Blk #22 wire from the solder lug to main power supply board ground and route with the secondary wires, with wraps at every 2 inches. Remove R61 (2.2K ohm) and R60 (470K ohm) on Power Supply PCB. Add Qty (2) 100K 1/4W and Qty (1) 680 ohm as shown. from ECO 900

Delete: R60 251-00078-03 2.2K 1/4W
R61 251-00134-00 470K 1/4W

Add: Qty. 2 251-00118-03 100K 1/4W
Qty. 1 251-00066-03 680 ohm
Qty. 1 111-20051-00 #6 lug
Qty 1 401-10502-00 wire #22 ga

To reduce noise in outputs,

DELETE

Qty 2 100K ohm 1/4W resistor (R60, R64)
251-00118-00

ADD

Qty 2 47k ohm 1/4W resistor (R60, R64)
251-00110-00
Qty 2 Bracket
101-22006-01
Qty 1 Transformer Shield
511-00005-00
Qty 2 #6-32 X 3/8" Machine Screw
151-20052-00
Qty 2 #6 Kepnut
152-10002-00
Qty 1 Nylon Edging 3.5"
104-00001-00

PROCEDURE

To install transformer shield:

1. Use the #6-32 X 3/8" machine screws (151-20052-00) and #6 kepnuts (152-10002-00) to attach the two brackets (101-22006-01) to the transformer shield (511-00005-00).
NOTE: Screws go through shield first and then through hole in short end of bracket. The long end of bracket should be nearest the bottom edge of the shield.
2. Install the nylon edging along the bottom edge of the shield.
3. Remove upper nut from the two transformer mounts on the right hand side of the transformer (side nearest speaker output binding posts). Install transformer shield assembly so that the holes in the long end of the two brackets are positioned over the transformer mounting bolts and the shield is positioned between the transformer and the speaker output binding posts (see Figure 1).
4. Re-install the two nuts onto the transformer mounts, over the transformer shield brackets.

NOTE: To further reduce noise:

- a) route transformer secondary wires beneath the transformer shield and under R99L and R99R.
- b) route twisted pairs on power supply board as close to the top of the board as possible.
- c) route wiring from filter caps as close to the power supply board as possible.

To change input impedance from 110k to 47k:

1. Replace R60 and R64 on the power supply board with 47k ohm 1/4W resistors (251-00110-00). See Figure 2.

CARVER CORPORATION SERVICE BULLETIN

Service Bulletin # TFM-45-5 Model: TFM-45/TFM-42 Serial nos. See page 1

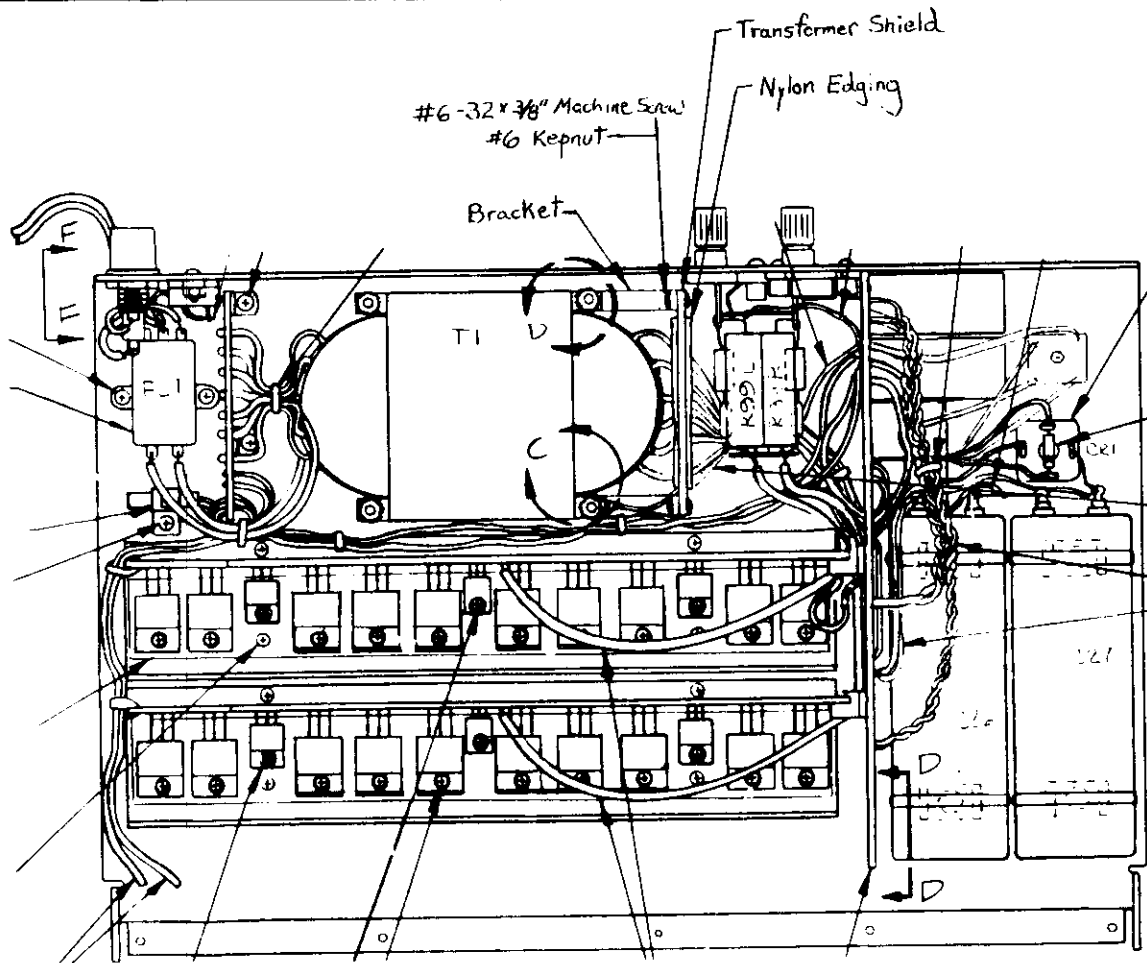

Figure 1

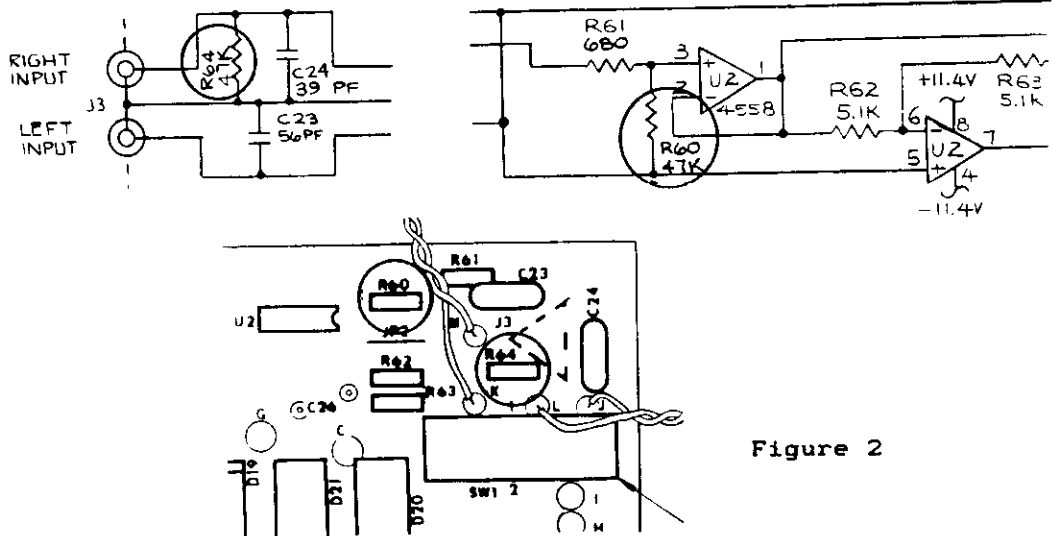

Figure 2

TFM-45/42 Power Supply PCB

CARVER CORPORATION SERVICE BULLETIN

Service Bulletin # TFM-45-6	Model: TFM-45	Serial Nos. As Needed
REASON: If customer complains of turn-off/turn-on thump.		Date: 4/12/91
DELETE	ADD	

PROCEDURE

Turn-off thump in the TFM-45 is caused by non-symmetrical discharging of the low rail supply voltage (+/-31Vdc). Because the meter lights cause an added drain on the +31Vdc supply, R69 and R70 load the -31Vdc supply to compensate. However, this may not entirely eliminate turn-off thump in every case, and further action may be necessary.

Before proceeding, in order to minimize noise/buzz/hum:

1. Verify that Service Bulletin TFM-45-3 has been performed. This removes D18-D21 and C26 from the power supply board, and adds an off-board bridge rectifier.
2. Verify that Service Bulletin TFM-45-5 has been performed. This adds a shield between the power transformer and the power supply board, and changes the input impedance from 110kΩ to 47kΩ.
3. Replace the 9" red/white and black twisted pair on the power supply board (connecting 'J,O' and 'L,N') with a 7" 3-conductor shielded twisted pair (i.e. Manhattan Electric M-3202 or equivalent). Tie the shield to 'L', which is signal ground near the input jack.

TEST FOR TURN-OFF/TURN-ON THUMP

1. Drive both channels with a 2kHz sine wave into 8 ohm loads. Monitor outputs with an analog AC Voltmeter and adjust the level for .775 Vrms output. Turn the meter dimmer pot fully clockwise (to the brightest position).
2. Turn the power switch off and verify turn-off thump is less than 1 Vrms on the meter. Monitor for about ten seconds.
3. Turn unit back on and verify less than 1 Vrms on the meter.

CURES

If no thump is visible on the meter using resistive loads, find out if the customer has AC coupled speakers. If so try shorting C5 (470μF/16V) on both amplifier boards. This can be done by shorting across the leads of C5 with buss wire, or by removing the capacitors and installing jumper wires in their place. This is not recommended for normal reactive speaker loads, because this modification may cause an increase in the dc offset at the outputs.

CARVER CORPORATION SERVICE BULLETIN

Service Bulletin # TFM-45-6

Model: TFM-45

Serial Nos. As Needed

If turn-off/turn-on thump exceeds 1 Vrms, try one or more of the following possible cures:

- A) Be sure the meter dimmer pot is fully clockwise. The setting of the meter dimmer pot will affect the loading on the +31Vdc supply.
- B) Verify that the 4558 IC's (U2) in the amplifier boards are either:

XR4558 (manufactured by Exar)
RC4558 (manufactured by Raytheon)

It has been found that other brands of 4558's can cause turn-off thumps and squeals in this particular application (not to mention more wide-band noise).

- C) Try swapping the 31Vdc filter capacitors (i.e., use the positive filter capacitor in the negative supply, and vice versa). Differences in capacitances may equalize the discharge rate of the supply at turn-off.
- D) If that doesn't help, try swapping the 67Vdc filter capacitors.
- E) Try adding a 3.6K 2W resistor from the +31Vdc supply to ground.
- F) Try adding four 6.8K 2W resistors in parallel from the -67Vdc supply to ground.
